(54) A radial piston pump, particularly a fuel injection pump for diesel engines.

(57) The pump comprises a body formed by two elements (2, 3) sealingly clamped together, between which is defined a central chamber (5) in which a drive shaft (6) carrying an eccentric (7) is rotatably mounted. A plurality of cylinders (9) which open into the central chamber (5) of the body (2, 3) and are arranged radially around the shaft (6) is mounted in one element (2) of the body (2, 3), and pistons (13) which cooperate with the eccentric (7) are slidably mounted therein. These cylinders (9) are in communication with a supply chamber (18) defined in the body (2, 3) between the first and second elements (2, 3). The supply chamber (18) is annular in shape and is formed in a position radially outside the central chamber (5).

At least one sealing member (31) for separating the supply chamber (18) from the central chamber (5) is interposed between the first and second elements (2, 3) of the body.

At least one passage (50) is formed in one (3) of the elements (2, 3) of the body to put the supply chamber (18) into communication with the central

chamber (5). An electrically-controlled device (51) is provided in this passage (50) and is adapted to control the flow of fluid through the passage (50) in a predetermined manner.

EP 0 304 750 A1

## A radial piston pump, particularly a fuel injection pump for diesel engines

The present invention relates to a radial piston pump and, more specifically, to a pump of the type defined in the preamble of the appended Claim 1.

The pump according to the invention is characterised in that at least one passage is formed in one of the elements of the pump body and is able to put the supply chamber into communication with the central chamber; electrically-operated control means being provided for enabling the controlled flow of fluid through the said passage.

By means of these control means (which may comprise, for example, a solenoid cut-off valve which can be piloted in an on/off mode by means of an electrical control signal, or a solenoid flow modulating valve) it is possible at the extreme to prevent communication between the supply chamber and the central chamber of the pump or, in some circumstances, when useful, to enable controlled communication between the central chamber and the supply chamber, for example, when slight pre-heating of the fuel to be pumped would be useful.

Further characteristics and advantages of the present invention will become clear from the detailed description which follows with reference to the appended drawings, provided by way of non-limiting example, in which:

Figure 1 is an axial section of a radial piston pump according to the invention.

Figures 2 and 3 are cross-sections taken on the lines II-II and III-III of Figure 1.

With reference to the drawings, a radial piston pump 1 according to the invention comprises a body formed by two elements 2 and 3 clamped together by means of bolts 4.

In the embodiment illustrated, the element 2 has an annular projection, indicated 2a, on its face facing the element 3. The element 3 of the pump body has a corresponding annular projection 3a facing and in contact with the end surface of the projection 2a of the element 2.

A central cavity or chamber is indicated 5 and is defined between the elements 2 and 3 of the pump body. A drive shaft 6 carrying an eccentric 7 is rotatably mounted in this chamber.

Three equi-angularly spaced apertures 8 are formed in the projecting portion 2a of the element 2 of the pump body, the axes of which intersect in correspondence with the axis of the drive shaft 6. A cylinder 9 is fixed in each of these apertures and is provided in known manner with an intake valve and a controlled valve, generally indicated 10 and 11. A respective piston 13 is mounted for sliding in the working chamber 12 formed in each cylinder. The end of each piston 13 facing the shaft 6 has a head

14 against which acts a helical spring 15 disposed around the cylinder and tending to urge the piston towards the eccentric 7.

The element 3 of the pump body is substantially cup-shaped and has a side wall 3b which surrounds the projecting portion 2a of the element 2 of the body with clearance.

A sealing ring 17 (Figure 1) is clamped between the upper portion of the wall 3b of the element 3 and the portion facing the outer lateral surface of the element 2 of the pump body.

An annular chamber defined in the pump body between the side wall 3b and the projecting portion 2a of the element 2 is indicated 18. This annular chamber acts as a supply or intake chamber of the pump and communicates with an inlet connector 19 (Figure 1) through a passage, indicated 20. The liquid which is to be pumped is supplied through this connector. In the case of a fuel injection pump in a diesel engine, this liquid is diesel oil.

The working chamber 12 of each cylinder can be put into communication with the chamber 18 through the respective intake valve 10, when the piston 13 effects its induction stroke under the action of the spring 15 which tends to keep it in contact with the surface of the eccentric 7. This working chamber can be put into communication with a delivery manifold through the respective delivery valve 11, however, when the associated piston 13, pushed by the eccentric 7, effects its delivery stroke.

An annular recess 30 housing a sealing ring 31 (Figure 1) is formed in that surface of the projecting portion 3a of the element 3 of the pump body which is in frontal contact with the projecting portion 2a of the element 2. This sealing ring, which is clamped between the two elements 2 and 3 of the pump body, ensures the sealed separation of the central chamber 5 from the supply chamber 18 of the pump.

Operating conditions can actually occur in which controlled pre-heating of the fuel to be pumped may be useful or desirable. With the pump according to the invention it is possible to achieve such controlled preheating of the fuel.

In the operation some fuel inevitably leaks between the pistons 13 and the cylinders 9 and flows into the central chamber 5. The fuel thus leaked into the chamber 5 is at a high temperature.

The central chamber 5 of the pump can be put into communication with the chamber 18 through a passage illustrated by broken lines in Figure 1 and indicated 50. An electrically-operated control device is associated with this passage and is adapted to control the flow of fuel between the chambers 5

and 18 through the passage 50. The control device 51 may comprise, for example, a solenoid cut-off valve which can be piloted in an on/off mode by means of an electrical control signal, or a solenoid flow-modulating valve.

The passage 50 may be closed completely by the control device 51, and in this case, the temperature of the fuel within the central chamber tends to increase without noticeably affecting the temperature of the fuel which is being pumped.

Moreover, the device 51 may be piloted so as to allow some communication between the chambers 5 and 18 in some circumstances, with a consequent increase in the temperature of the fuel pumped.

wall (3b) surrounds the projection (2a) of the first element (2) of the body in spaced relationship to define therewith the supply chamber (18).

4. A radial piston pump according to Claim 1, characterised in that the control means comprise a solenoid cut-off valve which can be piloted in an on/off mode by means of an electrical control signal.

5. A radial piston pump according to Claim 1, characterised in that the control means comprise solenoid flow-modulating valve.

### Claims

1. A radial piston pump comprising a body formed by two elements (2, 3) sealingly clamped together, between which is defined a central chamber (5) in which a drive shaft (6) carrying an eccentric (7) is rotatably mounted; a plurality of cylinders (9) which open into the central chamber (5) and are disposed radially around the shaft (6) being mounted in one element (2) of the body (2, 3) and pistons (13) which cooperate with the eccentric (7) being slidably mounted therein, the cylinders (9) being able to communicate with a supply chamber (18) defined in the body (2, 3) between the first and second elements (2, 3); the supply chamber (18) being annular in shape and formed in a position radially outside the central chamber (5); sealing means (31) for separating the supply chamber (18) from the central chamber (5) being provided between the first and second elements (2, 3) of the body; characterised in that at least one passage (50) is formed in one element (3) of the body (2, 3) and is able to put the supply chamber (18) into communication with the central chamber (5), electrically-operated control means (51) being provided to allow the controlled flow of fluid through the passage (50).

2. A radial piston pump according to Claim 1, characterised in that the element (2) of the body (2,3) in which the cylinders (9) are mounted has, on its surface facing the other element (3), an annular projection (2a) having seats (8) formed in equian- gularly spaced positions and in which the cylinders (9) are disposed, the other element (3) of the body (2, 3) having a surface (3a) clamped in contact with the projection (2a) of the first element (2) of the body with the interposition of at least one sealing member (31).

3. A radial piston pump according to Claim 2, characterised in that the other element (3) of the body (2, 3) is substantially cup-shaped and its side
